

Solutions to Enthalpy and Thermochemistry Problem Set

by: S.E. Van Bramer
Widener University 11/2/97

In the video clip from George Gobel you saw that it is possible to light a charcoal grill in about a minute. If the grill is prepared using one 20 pound bag of charcoal (primarily carbon) and two 1 gallon buckets of liquid oxygen (the density of LOX (liquid oxygen) is 1142 kg/m³, CRC Handbook of Chemistry and Physics.)

1. Write a balanced chemical equation describing this reaction.

2. Determine the limiting reagent for this reaction.

amount of carbon

$$\text{mass}_\text{C} := 20 \cdot \text{lb}$$

$$\text{mass}_\text{C} = 9.07185 \cdot 10^3 \cdot \text{gm}$$

$$\text{MW}_\text{C} := 12.0107 \cdot \text{gm} \cdot \text{mole}^{-1}$$

$$\text{mole}_\text{C} := \frac{\text{mass}_\text{C}}{\text{MW}_\text{C}}$$

$$\text{mole}_\text{C} = 755.3138 \cdot \text{mole}$$

amount of oxygen

$$V_{\text{O}_2} := 2 \cdot \text{gal}$$

$$V_{\text{O}_2} = 7.57082 \cdot 10^3 \cdot \text{mL}$$

$$\text{density}_{\text{O}_2} := 1142 \cdot \text{kg} \cdot \text{m}^{-3}$$

$$\text{density}_{\text{O}_2} = 1.142 \cdot \text{gm} \cdot \text{mL}^{-1}$$

$$\text{mass}_{\text{O}_2} := V_{\text{O}_2} \cdot \text{density}_{\text{O}_2}$$

$$\text{mass}_{\text{O}_2} = 8.64588 \cdot 10^3 \cdot \text{gm}$$

$$\text{MW}_{\text{O}_2} := 2 \cdot 15.9994 \cdot \text{gm} \cdot \text{mole}^{-1}$$

$$\text{MW}_{\text{O}_2} = 31.9988 \cdot \text{gm} \cdot \text{mole}^{-1}$$

$$\text{mole}_{\text{O}_2} := \frac{\text{mass}_{\text{O}_2}}{\text{MW}_{\text{O}_2}}$$

$$\text{mole}_{\text{O}_2} = 270.1939 \cdot \text{mole}$$

Since the equation is balanced with a 1:1 stoichiometry for C and O₂, an equal number of moles are required. Since there are fewer moles of O₂, this is the limiting reagent.

3. Calculate the mass of each product and any remaining reactant.

$$\text{mole O2}_{\text{final}} := \text{mole O2} - \text{mole O2}$$

$$\text{mole O2}_{\text{final}} = 0 \cdot \text{mole}$$

$$\text{mass O2}_{\text{final}} := \text{mole O2}_{\text{final}} \cdot \text{MW O2}$$

$$\text{mass O2}_{\text{final}} = 0 \cdot \text{gm}$$

$$\text{mole C}_{\text{final}} := \text{mole C} - \text{mole O2}$$

$$\text{mole C}_{\text{final}} = 485.11989 \cdot \text{mole}$$

$$\text{mass C}_{\text{final}} := \text{mole C}_{\text{final}} \cdot \text{MW C}$$

$$\text{mass C}_{\text{final}} = 5.82663 \cdot 10^3 \cdot \text{gm}$$

$$\text{mole CO2}_{\text{final}} := \text{mole O2}$$

$$\text{mole CO2}_{\text{final}} = 270.1939$$

$$\text{MW CO2} := (12.0107 + 2 \cdot 15.9994) \cdot \text{gm} \cdot \text{mole}^{-1}$$

$$\text{MW CO2} = 44.0095 \cdot \text{gm} \cdot \text{mole}^{-1}$$

$$\text{mass CO2} := \text{mole O2} \cdot \text{MW CO2}$$

$$\text{mass CO2} = 1.18911 \cdot 10^4 \cdot \text{gm}$$

4. Calculate the amount of heat released by this reaction.

$$\text{kJ} := 10^3 \cdot \text{joule}$$

$$\Delta H_{f_C} := 0 \cdot \text{kJ} \cdot \text{mole}^{-1}$$

$$\Delta H_{f_{O2}} := -4.812 \cdot \text{kJ} \cdot \text{mole}^{-1}$$

Value for O2 (l) at -80K, not 0 kJ mole⁻¹, since not at standard conditions.

$$\Delta H_{f_{CO2}} := -393.51 \cdot \text{kJ} \cdot \text{mole}^{-1}$$

$$\Delta H_{\text{rxn}} := \Delta H_{f_{CO2}} \cdot 1 \cdot \text{mole} - (\Delta H_{f_C} \cdot 1 \cdot \text{mole} + \Delta H_{f_{O2}} \cdot 1 \cdot \text{mole})$$

$$\Delta H_{\text{rxn}} = -388.698 \cdot \text{kJ}$$

$$\text{mole}_{\text{rxn}} := \text{mole O2}$$

$$\Delta H := \Delta H_{\text{rxn}} \cdot \text{mole}_{\text{rxn}}$$

$$\Delta H = -1.05024 \cdot 10^5 \cdot \text{kJ}$$

5.If this heat is used to warm a 500 gallon tank of water at 15 C, what is the final temperature?

$$E := -\Delta H$$

$$E = 1.05024 \cdot 10^5 \cdot \text{kJ}$$

$$V_{\text{H}_2\text{O}} := 500 \cdot \text{gal}$$

$$V_{\text{H}_2\text{O}} = 1.89271 \cdot 10^6 \cdot \text{mL}$$

$$\text{density}_{\text{H}_2\text{O}} := 999.1026 \cdot \text{kg} \cdot \text{m}^{-3}$$

$$\text{density}_{\text{H}_2\text{O}} = 0.9991 \cdot \text{gm} \cdot \text{mL}^{-1}$$

$$\text{mass}_{\text{H}_2\text{O}} := V_{\text{H}_2\text{O}} \cdot \text{density}_{\text{H}_2\text{O}}$$

$$\text{mass}_{\text{H}_2\text{O}} = 1.89101 \cdot 10^6 \cdot \text{gm}$$

$$C_{\text{H}_2\text{O}_1} := 4.2 \cdot \text{joule} \cdot \text{gm}^{-1} \cdot \text{K}^{-1}$$

$$E = \text{mass} \cdot C \cdot \Delta T$$

$$\Delta T_{\text{H}_2\text{O}} := \frac{E}{\text{mass}_{\text{H}_2\text{O}} \cdot C_{\text{H}_2\text{O}_1}}$$

$$\Delta T_{\text{H}_2\text{O}} = 13.22347 \cdot \text{K}$$

$$\Delta T = T_{\text{final}} - T_{\text{initial}}$$

$$T_{\text{initial}_{\text{H}_2\text{O}}} := (273.15 + 15) \cdot \text{K}$$

$$T_{\text{final}_{\text{H}_2\text{O}}} := \Delta T_{\text{H}_2\text{O}} + T_{\text{initial}_{\text{H}_2\text{O}}}$$

$$T_{\text{final}_{\text{H}_2\text{O}}} = 301.37347 \cdot \text{K}$$

$$T_{\text{final}_{\text{H}_2\text{O}}} \cdot \text{K}^{-1} - 273.15 = 28.22347$$

6.If this heat is used to warm 40 kg of ice at 200 K, what is the final temperature?

Constants

$$C_{\text{H}_2\text{O}_s} := 2.1 \cdot \text{joule} \cdot \text{gm}^{-1} \cdot \text{K}^{-1}$$

$$C_{\text{H}_2\text{O}_g} := 2.0 \cdot \text{joule} \cdot \text{gm}^{-1} \cdot \text{K}^{-1}$$

$$\Delta H_{\text{fusion}} := 333 \cdot \text{joule} \cdot \text{gm}^{-1}$$

$$\Delta H_{\text{vap}} := 2260 \cdot \text{joule} \cdot \text{gm}^{-1}$$

First step, warm to 273.15 K

$$\text{mass}_{\text{H}_2\text{O}} := 40 \cdot \text{kg}$$

$$\text{mass}_{\text{H}_2\text{O}} = 4 \cdot 10^4 \cdot \text{gm}$$

$$E_{\text{step}_1} := \text{mass}_{\text{H}_2\text{O}} \cdot (273.15 \cdot \text{K} - 200 \cdot \text{K}) \cdot C_{\text{H}_2\text{O}_s}$$

$$E_{\text{step}_1} = 6.1446 \cdot 10^3 \cdot \text{kJ}$$

$$E_{\text{remain}} := E - E_{\text{step}_1}$$

$$E_{\text{remain}} = 9.88792 \cdot 10^4 \cdot \text{kJ}$$

Second step, melt ice

$$E_{\text{step}_2} := \Delta H_{\text{fusion}} \cdot \text{mass}_{\text{H2O}} \quad E_{\text{step}_2} = 1.332 \cdot 10^4 \cdot \text{kJ}$$

$$E_{\text{remain}} := E - E_{\text{step}_1} - E_{\text{step}_2} \quad E_{\text{remain}} = 8.55592 \cdot 10^4 \cdot \text{kJ}$$

Third step, heat liquid water

$$E_{\text{step}_3} := \text{mass}_{\text{H2O}} \cdot (373.15 \cdot \text{K} - 273.15 \cdot \text{K}) \cdot C_{\text{H2O}_1}$$

$$E_{\text{step}_3} = 1.68 \cdot 10^4 \cdot \text{kJ}$$

$$E_{\text{remain}} := E - E_{\text{step}_1} - E_{\text{step}_2} - E_{\text{step}_3} \quad E_{\text{remain}} = 6.87592 \cdot 10^4 \cdot \text{kJ}$$

Fourth step, boil water

$$E_{\text{step}_4} := \Delta H_{\text{vap}} \cdot \text{mass}_{\text{H2O}}$$

$$E_{\text{step}_4} = 9.04 \cdot 10^4 \cdot \text{kJ}$$

$$E_{\text{remain}} := E - E_{\text{step}_1} - E_{\text{step}_2} - E_{\text{step}_3} - E_{\text{step}_4} \quad E_{\text{remain}} = -2.16408 \cdot 10^4 \cdot \text{kJ}$$

There is not sufficient energy available to boil all of the water, so only some of the water is converted into steam the final temperature would be 100 C, or 373.15 K.

The mass of water that does boil is determined by the amount of energy available.

$$\text{mass}_{\text{H2O_boil}} := \frac{E - E_{\text{step}_1} - E_{\text{step}_2} - E_{\text{step}_3}}{\Delta H_{\text{vap}}}$$

$$\text{mass}_{\text{H2O_boil}} = 30.42444 \cdot \text{kg}$$
